Abstract

The age and sex composition of populations varies substantially between and within countries, and is tightly intertwined to economic and health outcomes. This is particularly true for low- and middle-income countries, where the fast paced population increase is not nationally homogeneous but rather urban-driven, with important repercussions on health infrastructures, resources availability, internal migration and shifting dependency ratios. As a result of this, the association between population increase Indeed, population structure has long been considered to be a predictor for the development of nations, their economic growth, demographic burdens and challenges. In this context, the Sustainable Development Goals moral imperative of leaving no-one behind requires accurate measures at local scale that take into account high degrees of spatial heterogeneity present sub-nationally. However, the spatial detail is often overlooked losing substantial demographic variation, as preference for national-level measures is still widespread, due to longstanding practice in research and data availability. We aim to provide population based metrics of population exposures by 17 age-groups and sex detail at subnational level for all 248 countries in the world over a timeframe of 21 years.

Introduction

The age and sex composition of populations varies substantially between and within countries, and is tightly intertwined to economic and health outcomes. This is particularly true for low- and middle-income countries, where the fast-paced population increase is not nationally homogeneous but rather urban-driven, with important repercussions on health infrastructures, resources availability, internal migration and shifting dependency ratios. Population structure has long been considered to be a predictor for the development of nations, their economic growth, demographic burdens and challenges. In this context, the Sustainable Development Goals moral imperative of leaving no-one behind requires accurate measures at local scale that consider high degrees of spatial heterogeneity present sub-nationally. However, the spatial detail is often overlooked losing substantial demographic

variation, as preference for national-level measures is still widespread, due to longstanding practice in research and data availability.

This study provides mid-year population denominators by 17 age-groups and sex detail at subnational level for all 248 countries considered over a timeframe of 21 years.

Compiling subnational estimates of age and sex structures

Data on subnational population compositions from 2000 to 2020 were derived using a variety of data sources for all populated countries in the world, excluding unpopulated or military operated areas (i.e. Antarctica). The data sources used are recent and can be divided into three groups: census based, register based, and survey based.

Contemporary census-based counts are broken down at administrative unit level and generally provide the most reliable source for population composition, due to the large sample sizes supplying reliable information summarized for small areas. Census based sources (census and IPUMSI) with age and sex data reported at subnational levels were employed if undertaken since year 2000. Census counts were aligned to be mid-year population estimates (1st July of the calendar year), and age-sex based counts grouped into the relevant age groups. The subnational population age and sex structure was grouped into 5-years age groups up to 80 year old (abridged) for a total of 17 age groups and 2 sexes. Due to the importance of having detailed information on child and infant related statistics (i.e. child and infant mortality), the age group 0-4 was split in two groups: population under 1 year of age and between 1 and 4 years old. All counts are mid-year population estimated at the 1st of July, to allow a ready use of population numbers as denominators for demographic rates. The transformation from Census date to mid-year population was implemented using UN growth rates applied to the Census data (see UN manual I, ch. 4 p. 25).

Contrary to census data, which is usually collected every 10 years, EUROSTAT collects data every year, with countries reporting to EUROSTAT their population on the 1st of January, along with breakdowns of the population by various characteristics, resulting in abundance of information on European population also at subnational level with yearly updates mainly from the National Statistical Institutes.

Survey based sources provide samples of household-level records that offer age and sex structures, usually by administrative level 1 (e.g., province) or 2 (e.g., district). While census data are often readily available for high-income countries, for low-income countries, census data with subnational detail of age and sex structure can often be either unavailable or very old. To overcome this deficiency, national household survey data sources were employed to provide the most up to date and spatially detailed estimates as possible. Therefore, national household survey data on population age and sex compositions were obtained from the most recent Demographic and Health Survey (DHS), or from Multiple Indicator Cluster Surveys

(MICS). Subnational age and sex proportions were used to obtain population counts, based on the UN population total estimates for a specific country.

Where neither census nor surveys at subnational level were available, we employed national estimates of age and sex structures for 58 countries, coming from EUROSTAT, UN, and US Census Bureau for countries with less than 15,000 inhabitants.

Table 1 describes all the data sources complete with reference years and number of administrative units employed for the realization of the denominator index. Population age structures by age and sex have been estimated for all countries at subnational level, by 5 years age groups, with the addition of children under 1 and children between 1 and 4 years old (also by sex), given the importance that those two age groups represent for health measures.

<u>Methodology</u>

The standard approach adopted to produce age and sex structures at subnational level when data are available for one year only (i.e. a Census) is Iterative Proportional Fitting (IPF). After obtaining the mid-year population counts at sub-national level, we employ IPF using UN population estimates as target population for the year to be predicted. The Iterative Proportional Fitting method takes into account age and sex group population distributions in the subnational areas. The base for calculating the mid-year population age and sex groups. The numbers are prorated by a series of iterations to two sets of controls for that target date: UN midyear 0-1, 1-4, and successive 5-year age and sex group population projections for the country and the total population estimates for the subnational areas or national whenever the subnational estimates are not available.

The IPF method requires a two-step procedure, one where the subnational area age groups (both males and females) are raked to the corresponding UN midyear projected national population for that age group. Age and sex group repeats this process until the iterations lead to the same estimates. The number of iterations has been programmed through RCran and set arbitrarily to 30, which abundantly ensures convergence. These steps are then repeated to estimate each year of the time series. IPF input years are then smoothed against UN total population estimates to avoid a jump between estimated years and the observed year, maintaining intact the age and sex structure at subnational level in the observed year.

When more than one year is available, we apply a trend method: shift share and IPF. Trend methods, have the advantage of allowing for different growth patterns across each subnational area, as controls can be calculated based on the population growth rates of the individual subnational areas relative to the country. This means that if a region grows more quickly with respect to the national growth rate then the shift share will capture this trend. The Shift-Share method can be used to compute a population estimate for a subnational area for a target date based on the linear rate of growth of its share of the country's

population between two censuses. With the Shift- Share method, it is possible to obtain the average annual rate of change of the ratio of the population of each subnational area between the country's latest two censuses. Then the intercensal rate of change is extrapolated to the target year to yield a new ratio. With the projected national population from the UN estimates for a specific target midyear it is possible to estimate a target population for each subnational area for the target midyear.

Some countries with very small populations (i.e. Pacific islands), do not have population estimates with age and sex detail for target years within out time-series. In this case, we employed a pro-rating technique. Pro-rating distributes the population observed on the census date to a more recent date, keeping sex and age in the same proportions as those observed at the census (Manual III, ch. 2, A.49). This method is implemented by finding the ratio between the total population on two dates, then multiplying all the observed numbers in each sex-age category by such ratio. This method has been applied for countries with small populations, where yearly estimates of total population were available, thus updating the incremental ratio yearly.

For those countries with no subnational detail, we used United Nations and US Census Bureau national estimates, highlighted in table one in column 3 whenever "Administrative Units" equals 1.

Results and validation

The results have been validated selecting countries with multiple data sources and applying measures of precision and bias. The dataset has been further employed to obtain fine grid scale data at 100m grid cells.

Map 1. Old dependency ratio for year 2020 at administrative unit level.

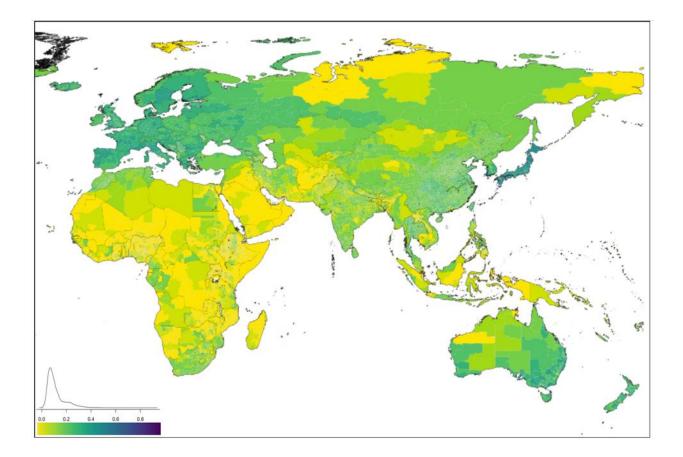

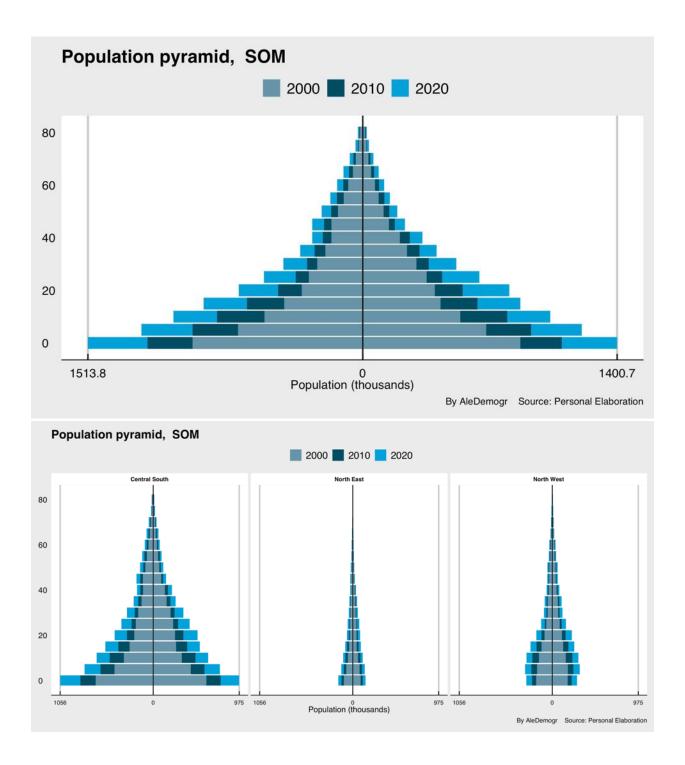

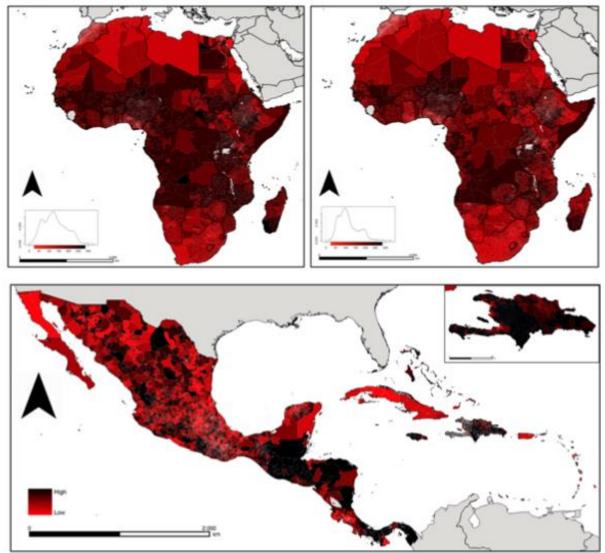

Figure 1. Population between 2000 and 2020 at national and administrative level for Somalia.

Map 2. General fertility rate for year 2000 (left and lower panels) and 2020 (right panel).

The dataset is available for use at high resolution gridded population counts for every age and sex category for the whole 2000-2020 time frame at ~100x100m grid cell resolution https://www.worldpop.org/geodata/listing?id=29 and at 1kmx1km resolution https://www.worldpop.org/geodata/listing?id=29 and at 1kmx1km resolution
